# Package 'pedmod'

October 14, 2022

```
based on direct log marginal likelihood approximations like the randomized
     Quasi-Monte Carlo suggested by <doi:10.1198/106186002394> with a similar
     procedure to approximate the derivatives. The minimax tilting method
     suggested by <doi:10.1111/rssb.12162> is also supported. Graph-based methods
     are also provided that can be used to simplify pedigrees.

Maintainer Benjamin Christoffersen <booknood@gmail.com>

**Description** Provides functions to estimate mixed probit models using, for

commonly called liability threshold models. The approximation is

instance, pedigree data like in <doi:10.1002/sim.1603>. The models are also

biconnected\_components

Finds the Biconnected Components

## Description

Finds the biconnected components and the cut vertices (articulation points) using the methods suggested by Hopcroft et al. (1973).

## Usage

```
biconnected_components(from, to)
biconnected_components_pedigree(id, father.id, mother.id)
```

#### **Arguments**

from	integer vector with one of the vertex ids.
to	integer vector with one of the vertex ids.
id	integer vector with the child id.
father.id	integer vector with the father id. May be NA if it is missing.
mother.id	integer vector with the mother id. May be NA if it is missing.

#### Value

A list with vectors of vertices in each biconnected component. An attribute called "cut\_verices" contains the cut vertices in each biconnected component.

#### References

Hopcroft, J., & Tarjan, R. (1973). *Algorithm 447: efficient algorithms for graph manipulation*. Communications of the ACM, 16(6), 372-378.

all.equal(out_pedigree, out)</pre>
```

block\_cut\_tree

Creates a Block-cut Tree Like Object

## **Description**

Creates a block-cut tree like structure computed using the method suggested by Hopcroft et al. (1973).

## Usage

```
block_cut_tree(from, to)
block_cut_tree_pedigree(id, father.id, mother.id)
```

## **Arguments**

from integer vector with one of the vertex ids.

to integer vector with one of the vertex ids.

id integer vector with the child id.

father.id integer vector with the father id. May be NA if it is missing.

mother.id integer vector with the mother id. May be NA if it is missing.

## Value

A tree structure where each node is represented as list that contains the vertices in the biconnected component, the cut\_vertices, and the node's leafs.

## References

eval\_pedigree\_ll

Approximate the Log Marginal Likelihood

## Description

Approximate the log marginal likelihood and the derivatives with respect to the model parameters.

## Usage

```
eval_pedigree_ll(
```

```
ptr,
  par,
 maxvls,
  abs_eps,
  rel_eps,
  indices = NULL,
 minvls = -1L,
 do_reorder = TRUE,
  use_aprx = FALSE,
 n_{threads} = 1L,
  cluster_weights = NULL,
  standardized = FALSE,
 method = 0L,
 use_tilting = FALSE,
 vls\_scales = NULL
)
eval_pedigree_grad(
 ptr,
 par,
 maxvls,
 abs_eps,
  rel_eps,
  indices = NULL,
 minvls = -1L,
 do_reorder = TRUE,
  use_aprx = FALSE,
  n_{threads} = 1L,
  cluster_weights = NULL,
  standardized = FALSE,
 method = 0L,
 use_tilting = FALSE,
  vls_scales = NULL
)
eval_pedigree_hess(
 ptr,
 par,
 maxvls,
 abs_eps,
  rel_eps,
  indices = NULL,
 minvls = -1L,
 do_reorder = TRUE,
  use_aprx = FALSE,
  n_{threads} = 1L,
  cluster_weights = NULL,
  standardized = FALSE,
```

```
method = 0L,
use_tilting = FALSE,
vls_scales = NULL
)
```

## Arguments

ptr	object from pedigree_ll_terms or pedigree_ll_terms_loadings.
par	numeric vector with parameters. For an object from pedigree_ll_terms these are the fixed effect coefficients and log scale parameters. The log scale parameters should be last. For an object from pedigree_ll_terms_loadings these are the fixed effects and the coefficients for scale parameters.
maxvls	maximum number of samples in the approximation for each marginal likelihood term.
abs_eps	absolute convergence threshold.
rel_eps	relative convergence threshold.
indices	zero-based vector with indices of which log marginal likelihood terms to include. Use NULL if all indices should be used.
minvls	minimum number of samples for each marginal likelihood term. Negative values provides a default which depends on the dimension of the integration.
do_reorder	TRUE if a heuristic variable reordering should be used. TRUE is likely the best value.
use_aprx	TRUE if a less precise approximation of pnorm and qnorm should be used. This may reduce the computation time while not affecting the result much.
n_threads	number of threads to use.
cluster_weight	
	numeric vector with weights for each cluster. Use NULL if all clusters have weight one.
standardized	<pre>logical for whether to use the standardized or direct parameterization. See standardized_to_direct and the vignette at vignette("pedmod", package = "pedmod").</pre>
method	integer with the method to use. Zero yields randomized Korobov lattice rules while one yields scrambled Sobol sequences.
use_tilting	TRUE if the minimax tilting method suggested by Botev (2017) should be used. See doi:10.1111/rssb.12162.
vls_scales	can be a numeric vector with a positive scalar for each cluster. Then vls_scales[i] * minvls and vls_scales[i] * maxvls is used for cluster i rather than minvls and maxvls. Set vls_scales = NULL if the latter should be used.

## **Details**

 $\verb| eval_pedigree_hess| is only implemented for objects from \verb| pedigree_ll_terms|.$ 

#### Value

eval\_pedigree\_11: a scalar with the log marginal likelihood approximation. It has an attribute called "n\_fails" which shows the number of log marginal likelihood term approximations which do not satisfy the abs\_eps and rel\_eps criteria and an attribute called std with a standard error estimate based on the delta rule.

eval\_pedigree\_grad: a vector with the derivatives with respect to par. An attribute called "logLik" contains the log marginal likelihood approximation. There will also be "n\_fails" attribute like for eval\_pedigree\_ll and an attribute called "std" which first element is the standard error estimate of the log likelihood based on the delta method and the last elements are the standard error estimates of the gradient. The latter ignores the Monte Carlo error from the likelihood approximation.

eval\_pedigree\_hess: a matrix with the hessian with respect to par. An attribute called "logLik" contains the log marginal likelihood approximation and an attribute called "grad" contains the gradient. The attribute "hess\_org" contains the Hessian with the scale parameter on the identity scale rather than the log scale. "vcov" and "vcov\_org" are the covariance matrices from the hessian and "hess\_org".

max\_balanced\_partition

Finds an Approximately Balanced Connected Partition

## **Description**

Uses the method suggested by Chlebíková (1996) to construct an approximate maximally balanced connected partition. A further refinement step can be made to reduce the cost of the cut edges. See vignette("pedigree\_partitioning", package = "pedmod") for further details.

## Usage

```
max_balanced_partition(
  from,
  to,
  weight_data = NULL,
  edge_weights = NULL,
  slack = 0,
 max_kl_it_inner = 50L,
 \max_{kl_i} = 10000L,
  trace = 0L,
  check_weights = TRUE,
  do_reorder = FALSE
)
max_balanced_partition_pedigree(
  id,
  father.id,
 mother.id,
  id_weight = NULL,
  father_weight = NULL,
  mother_weight = NULL,
  slack = 0,
 max_kl_it_inner = 50L,
 \max_{kl_i} = 10000L,
  trace = 0L,
  check_weights = TRUE,
  do_reorder = FALSE
)
```

## Arguments

from	integer vector with one of the vertex ids.	
to	integer vector with one of the vertex ids.	
weight_data	list with two elements called "id" for the id and "weight" for the vertex weight. All vertices that are not in this list have a weight of one. Use NULL if all vertices have a weight of one.	
edge_weights	numeric vector with weights for each edge. Needs to have the same length as from and to. Use NULL if all edges should have a weight of one.	
slack	fraction between zero and 0.5 for the allowed amount of deviation from the balance criterion that is allowed to reduce the cost of the cut edges.	
max_kl_it_inner		
	maximum number of moves to consider in each iteration when slack $> 0$ .	
max_kl_it	maximum number of iterations to use when reducing the cost of the cut edges. Typically the method converges quickly and this argument is not needed.	
trace	integer where larger values yields more information printed to the console during the procedure.	

logical for whether to check the weights in each biconnected component. This check\_weights may fail if the graph is not connected in which case the results will likely be wrong. It may also fail for large graphs because of floating-point arithmetic. The latter is not an error and the reason for this argument. do\_reorder logical for whether the implementation should reorder the vertices. This may reduce the computation time for some data sets. id integer vector with the child id. father.id integer vector with the father id. May be NA if it is missing. mother.id integer vector with the mother id. May be NA if it is missing. numeric vector with the weight to use for each vertex (individual). NULL yields id\_weight a weight of one for all. father\_weight weights of the edges created between the fathers and the children. Use NULL if all should have a weight of one. weights of the edges created between the mothers and the children. Use NULL if mother\_weight

#### Value

A list with the following elements:

balance\_criterion

value of the balance criterion.

all should have a weight of one.

removed\_edges 2D integer matrix with the removed edges.

set\_1, set\_2 The two sets in the partition.

mvndst

Multivariate Normal Distribution CDF and Its Derivative

#### Description

Provides an approximation of the multivariate normal distribution CDF over a hyperrectangle and the derivative with respect to the mean vector and the covariance matrix.

## Usage

```
mvndst(
  lower,
  upper,
  mu,
  sigma,
  maxvls = 25000L,
  abs_eps = 0.001,
  rel_eps = 0L,
  minvls = -1L,
```

14 mvndst

```
do_reorder = TRUE,
  use_aprx = FALSE,
 method = 0L,
 n_{sequences} = 8L,
  use_tilting = FALSE
)
mvndst_grad(
  lower,
  upper,
 mu,
  sigma,
 maxvls = 25000L,
 abs_{eps} = 0.001,
  rel_eps = 0L,
 minvls = -1L,
  do_reorder = TRUE,
  use_aprx = FALSE,
 method = 0L,
 n_{sequences} = 8L,
 use_tilting = FALSE
)
```

## Arguments

lower

upper	numeric vector with upper bounds.
mu	numeric vector with means.
sigma	covariance matrix.
maxvls	maximum number of samples in the approximation.
abs_eps	absolute convergence threshold.
rel_eps	relative convergence threshold.
minvls	minimum number of samples. Negative values provides a default which depends on the dimension of the integration.
do_reorder	TRUE if a heuristic variable reordering should be used. TRUE is likely the best value.
use_aprx	TRUE if a less precise approximation of pnorm and qnorm should be used. This may reduce the computation time while not affecting the result much.
method	integer with the method to use. Zero yields randomized Korobov lattice rules while one yields scrambled Sobol sequences.
n_sequences	number of randomized quasi-Monte Carlo sequences to use. More samples yields a better estimate of the error but a worse approximation. Eight is used in the original Fortran code. If one is used then the error will be set to zero because it cannot be estimated.
use_tilting	TRUE if the minimax tilting method suggested by Botev (2017) should be used.

numeric vector with lower bounds.

See doi:10.1111/rssb.12162.

mvndst 15

#### Value

mvndst: An approximation of the CDF. The "n\_it" attribute shows the number of integrand evaluations, the "inform" attribute is zero if the requested precision is achieved, and the "abserr" attribute shows 3.5 times the estimated standard error.

mvndst\_grad: A list with

- likelihood: the likelihood approximation.
- d\_mu: the derivative with respect to the the mean vector.
- d\_sigma: the derivative with respect to the covariance matrix ignoring the symmetry (i.e. working the  $n^2$  parameters with n being the dimension rather than the n(n+1)/2 free parameters).

pedigree\_ll\_terms

Get a C++ Object for Log Marginal Likelihood Approximations

#### **Description**

Constructs an object needed for eval\_pedigree\_ll and eval\_pedigree\_grad.

pedigree\_II\_terms 17

## Usage

```
pedigree_ll_terms(data, max_threads = 1L, n_sequences = 8L)
pedigree_ll_terms_loadings(data, max_threads = 1L, n_sequences = 8L)
```

## **Arguments**

data

list where each element is a list for a cluster with an:

- "X" element with the design matrix for the fixed effect,
- "Z" element with the design matrix for the loadings of the effects (only needed for pedigree\_ll\_terms\_loadings),
- "y" element with the zero-one outcomes, and
- "scale\_mats" element with a list where each element is a scale/correlation matrix for a particular type of effect.

max\_threads

maximum number of threads to use.

n\_sequences

number of randomized quasi-Monte Carlo sequences to use. More samples yields a better estimate of the error but a worse approximation. Eight is used in the original Fortran code. If one is used then the error will be set to zero because it cannot be estimated.

#### **Details**

An intercept column is not added to the X matrices like what lm.fit and glm.fit do. Thus, it is often important that the user adds an intercept column to these matrices as it is hardly ever justified to not include the intercept (the exceptions being e.g. when splines are used which include the intercept and with certain dummy designs). This equally holds for the Z matrices with pedigree\_ll\_terms\_loadings.

pedigree\_ll\_terms\_loadings relax the assumption that the scale parameter is the same for all individuals. pedigree\_ll\_terms\_loadings and pedigree\_ll\_terms yield the same model if "Z" is an intercept column for all families but with a different parameterization. In this case, pedigree\_ll\_terms will be faster. See vignette("pedmod", "pedmod") for examples of using pedigree\_ll\_terms\_loadings.

pedmod\_opt

Optimize the Log Marginal Likelihood

## **Description**

Optimizes eval\_pedigree\_11 and eval\_pedigree\_grad using a passed optimization function.

## Usage

```
pedmod_opt(
  ptr,
  par,
 maxvls,
  abs_eps,
  rel_eps,
  opt_func = NULL,
  seed = 1L,
  indices = NULL,
  minvls = -1L,
  do_reorder = TRUE,
  use_aprx = FALSE,
  n_{threads} = 1L,
  cluster_weights = NULL,
  fix = NULL,
  standardized = FALSE,
 method = 0L,
  use_tilting = FALSE,
  vls_scales = NULL,
)
pedmod_start(
  ptr,
  data,
 maxvls = 1000L,
  abs_eps = 0,
  rel_{eps} = 0.01,
  seed = 1L,
  indices = NULL,
  scale_max = 9,
 minvls = 100L,
  do_reorder = TRUE,
  use_aprx = TRUE,
  n_{threads} = 1L,
  cluster_weights = NULL,
  standardized = FALSE,
  method = 0L,
  sc_start = NULL,
  use_tilting = FALSE,
  vls\_scales = NULL
)
pedmod_start_loadings(
  ptr,
  data,
  indices = NULL,
```

```
cluster_weights = NULL,
  sc_start_invariant = NULL
)
```

## Arguments

1 }	guments	
	ptr	object from pedigree_ll_terms or pedigree_ll_terms_loadings.
	par	starting values passed to opt_func.
	maxvls	maximum number of samples in the approximation for each marginal likelihood term.
	abs_eps	absolute convergence threshold for eval_pedigree_ll and eval_pedigree_grad.
	rel_eps	rel_eps convergence threshold for eval_pedigree_ll and eval_pedigree_grad.
	opt_func	function to perform minimization with arguments like optim. BFGS is used with optim if this argument is NULL.
	seed	seed to pass to set.seed before each gradient and function evaluation. Use NULL if the seed should not be fixed.
	indices	zero-based vector with indices of which log marginal likelihood terms to include. Use NULL if all indices should be used.
	minvls	minimum number of samples for each marginal likelihood term. Negative values provides a default which depends on the dimension of the integration.
	do_reorder	TRUE if a heuristic variable reordering should be used. TRUE is likely the best value.
	use_aprx	TRUE if a less precise approximation of pnorm and qnorm should be used. This may reduce the computation time while not affecting the result much.
	n_threads	number of threads to use.
	cluster_weights	
		numeric vector with weights for each cluster. Use NULL if all clusters have weight one.
	fix	integer vector with indices of par to fix. This is useful for computing profile likelihoods. NULL yields all parameters.
	standardized	<pre>logical for whether to use the standardized or direct parameterization. See standardized_to_direct and the vignette at vignette("pedmod", package = "pedmod").</pre>
	method	integer with the method to use. Zero yields randomized Korobov lattice rules while one yields scrambled Sobol sequences.
	use_tilting	TRUE if the minimax tilting method suggested by Botev (2017) should be used. See doi:10.1111/rssb.12162.
	vls_scales	can be a numeric vector with a positive scalar for each cluster. Then vls_scales[i] * minvls and vls_scales[i] * maxvls is used for cluster i rather than minvls and maxvls. Set vls_scales = NULL if the latter should be used.
		Arguments passed to opt_func.
	data	the list that was passed to pedigree_ll_terms or pedigree_ll_terms_loadings.

scale_max	the maximum value for the scale parameters. Sometimes, the optimization method tends to find large scale parameters and get stuck. Setting a maximum solves this.
sc_start	starting value for the scale parameters. Use NULL if you have no value to start with. $ \\$
sc_start_invariant	
	scale parameter(s) like sc_start. It is the value that all individuals should have (i.e. not one that varies by individual).

## Details

pedmod\_start and pedmod\_start\_loadings yield starting values which can be used for pedmod\_opt.
The methods are based on a heuristics.

#### Value

pedmod\_opt: The output from the opt\_func argument. Thus, if fix is supplied then this is optimal values of only par[-fix] with par[fix] being fixed to the inputs. Thus, the length is only the number of non-fixed parameters.

pedmod\_start: A list with:

- par: the starting value.
- beta\_no\_rng: the fixed effects MLEs without random effects.
- logLik\_no\_rng: the log maximum likelihood without random effects.
- logLik\_est: the likelihood at par.

pedmod\_start\_loadings: A list with:

- par: the starting value.
- beta\_no\_rng: the fixed effects MLEs without random effects.
- logLik\_no\_rng: the log maximum likelihood without random effects.

pedmod\_profile 23

pedmod\_profile

Computes Profile Likelihood Based Confidence Intervals

## Description

Computes likelihood ratio based confidence intervals for one the parameters in the model.

## Usage

```
pedmod_profile(
 ptr,
 par,
 delta,
 maxvls,
 minvls = -1L,
  alpha = 0.05,
  abs_eps,
  rel_eps,
 which_prof,
  indices = NULL,
 maxvls_start = max(100L, as.integer(ceiling(maxvls/5))),
 minvls_start = if (minvls < 0) minvls else minvls/5,
  do_reorder = TRUE,
  use_aprx = FALSE,
  n_{threads} = 1L,
  cluster_weights = NULL,
 method = 0L,
  seed = 1L,
  verbose = FALSE,
 max_step = 15L,
  standardized = FALSE,
  use_tilting = FALSE,
  vls_scales = NULL,
)
```

## **Arguments**

ptr	object from pedigree_ll_terms or pedigree_ll_terms_loadings.
par	numeric vector with the maximum likelihood estimator e.g. from pedmod_opt.
delta	numeric scalar with an initial step to take. Subsequent steps are taken by 2^( <iteration number=""> - 1) * delta. Two times the standard error is a good value or a guess thereof. Hessian approximations are not implemented as of this writing and therefore the user needs to provide some guess.</iteration>
maxvls	maximum number of samples in the approximation for each marginal likelihood term.

24 pedmod\_profile

minimum number of samples for each marginal likelihood term. Negative values minvls provides a default which depends on the dimension of the integration. alpha numeric scalar with the confidence level required. absolute convergence threshold for eval\_pedigree\_11 and eval\_pedigree\_grad. abs\_eps rel\_eps rel\_eps convergence threshold for eval\_pedigree\_ll and eval\_pedigree\_grad. integer scalar with index of the parameter which the profile likelihood curve which\_prof should be computed for. indices zero-based vector with indices of which log marginal likelihood terms to include. Use NULL if all indices should be used. maxvls\_start, minvls\_start number of samples to use when finding the initial values for the optimization. do\_reorder TRUE if a heuristic variable reordering should be used. TRUE is likely the best use\_aprx TRUE if a less precise approximation of pnorm and qnorm should be used. This may reduce the computation time while not affecting the result much. n threads number of threads to use. cluster\_weights numeric vector with weights for each cluster. Use NULL if all clusters have method integer with the method to use. Zero yields randomized Korobov lattice rules while one yields scrambled Sobol sequences. seed to pass to set. seed before each gradient and function evaluation. Use seed NULL if the seed should not be fixed. logical for whether output should be printed to the console during the estimation verbose of the profile likelihood curve. max\_step integer scalar with the maximum number of steps to take in either directions. standardized logical for whether to use the standardized or direct parameterization. See standardized\_to\_direct and the vignette at vignette("pedmod", package = "pedmod"). TRUE if the minimax tilting method suggested by Botev (2017) should be used. use\_tilting See doi:10.1111/rssb.12162. can be a numeric vector with a positive scalar for each cluster. Then vls\_scales[i] vls\_scales \* minvls and vls\_scales[i] \* maxvls is used for cluster i rather than minvls and maxvls. Set vls\_scales = NULL if the latter should be used. arguments passed on to pedmod\_opt.

#### Value

A list with the following elements:

confs 2D numeric vector with the profile likelihood based confidence interval.

the points at which the profile likelihood is evaluated.

p\_log\_Lik the log profile likelihood values at xs.

data list with the returned objects from pedmod\_opt.

## **Description**

Computes Profile Likelihood Based Confidence Intervals for a Nonlinear Transformation of the Variables

## Usage

```
pedmod_profile_nleq(
  ptr,
  par,
  maxvls,
  minvls = -1L,
  alpha = 0.05,
  abs_eps,
  rel_eps,
  heq,
  heq_bounds = c(-Inf, Inf),
  delta,
  indices = NULL,
```

pedmod\_profile\_nleq 27

```
maxvls_start = max(100L, as.integer(ceiling(maxvls/5))),
minvls_start = if (minvls < 0) minvls else minvls/5,
do_reorder = TRUE,
use_aprx = FALSE,
n_threads = 1L,
cluster_weights = NULL,
method = 0L,
seed = 1L,
verbose = FALSE,
max_step = 15L,
use_tilting = FALSE,
vls_scales = NULL,
control.outer = list(itmax = 100L, method = "BFGS", kkt2.check = FALSE, trace = FALSE),
control.optim = list(fnscale = get_n_terms(ptr)),
...
)</pre>
```

## **Arguments**

ptr	object from pedigree_ll_terms or pedigree_ll_terms_loadings.	
par	numeric vector with the maximum likelihood estimator e.g. from pedmod_opt.	
maxvls	maximum number of samples in the approximation for each marginal likelihood term.	
minvls	minimum number of samples for each marginal likelihood term. Negative values provides a default which depends on the dimension of the integration.	
alpha	numeric scalar with the confidence level required.	
abs_eps	$absolute\ convergence\ threshold\ for\ eval\_pedigree\_11\ and\ eval\_pedigree\_grad.$	
rel_eps	$rel\_eps~convergence~threshold~for~eval\_pedigree\_l1~and~eval\_pedigree\_grad.$	
heq	function that returns a one dimensional numerical vector which should be pro- filed. It does not need to evaluate to zero at the maximum likelihood estimator.	
heq_bounds	two dimensional numerical vector with bounds for heq.	
delta	numeric scalar with an initial step to take. Subsequent steps are taken by 2^( <iteration number=""> - 1) * delta. Two times the standard error is a good value or a guess thereof. Hessian approximations are not implemented as of this writing and therefore the user needs to provide some guess.</iteration>	
indices	zero-based vector with indices of which log marginal likelihood terms to include. Use NULL if all indices should be used.	
maxvls_start, minvls_start		
	number of samples to use when finding the initial values for the optimization.	
do_reorder	TRUE if a heuristic variable reordering should be used. TRUE is likely the best value.	
use_aprx	TRUE if a less precise approximation of pnorm and qnorm should be used. This may reduce the computation time while not affecting the result much.	
n_threads	number of threads to use.	

```
cluster_weights
                  numeric vector with weights for each cluster. Use NULL if all clusters have
                  weight one.
                  integer with the method to use. Zero yields randomized Korobov lattice rules
method
                  while one yields scrambled Sobol sequences.
seed
                  seed to pass to set. seed before each gradient and function evaluation. Use
                  NULL if the seed should not be fixed.
                  logical for whether output should be printed to the console during the estimation
verbose
                  of the profile likelihood curve.
max_step
                  integer scalar with the maximum number of steps to take in either directions.
                  TRUE if the minimax tilting method suggested by Botev (2017) should be used.
use_tilting
                  See doi:10.1111/rssb.12162.
                  can be a numeric vector with a positive scalar for each cluster. Then vls_scales[i]
vls_scales
                  * minvls and vls_scales[i] * maxvls is used for cluster i rather than minvls
                  and maxvls. Set vls_scales = NULL if the latter should be used.
control.outer, control.optim, ...
                  arguments passed to auglag
```

  use_tilting = FALSE,
  vls_scales = NULL,
```

pedmod\_profile\_prop 31

```
bound = c(0.01, 0.99), ...
```

## Arguments

nameric vector with the maximum likelihood estimator e.g. from pedmod_opt.  maxvls  maximum number of samples in the approximation for each marginal likelihood  term.  minvls  minimum number of samples for each marginal likelihood term. Negative values  provides a default which depends on the dimension of the integration.  alpha  numeric scalar with the confidence level required.  abs_eps  absolute convergence threshold for eval_pedigree_ll and eval_pedigree_grad.  rel_eps  rel_eps convergence threshold for eval_pedigree_ll and eval_pedigree_grad.  which_prof  the index of the random effect which proportion of variance should be profiled.  indices  zero-based vector with indices of which log marginal likelihood terms to include. Use NULL if all indices should be used.  maxvls_start  number of samples to use when finding the initial values for the optimization.  do_reorder  TRUE if a heuristic variable reordering should be used. TRUE is likely the best value.  use_aprx  TRUE if a less precise approximation of pnorm and qnorm should be used. This may reduce the computation time while not affecting the result much.  n_threads  cluster_weights  number of threads to use.  method  integer with the method to use. Zero yields randomized Korobov lattice rules while one yields scrambled Sobol sequences.  seed  seed to pass to set.seed before each gradient and function evaluation. Use NULL if the seed should not be fixed.  verbose  logical for whether output should be printed to the console during the estimation of the profile likelihood curve.  max_step  integer scalar with the maximum number of steps to take in either directions.  function to perform minimization with arguments like optim. BFGS is used with optim if this argument is NULL.  use_tilting  TRUE if the minimax tilting method suggested by Botev (2017) should be used.  See doi:10.1111/rssb.12162.  vls_scales  can be a numeric vector with a positive scalar for each cluster. Then vls_scales[i] * minvls and wavls. Set vls_scales[i] * maxvls is used for cluster i	ptr	object from pedigree_ll_terms.
minvls minimum number of samples for each marginal likelihood term. Negative values provides a default which depends on the dimension of the integration.  alpha numeric scalar with the confidence level required.  abs_eps absolute convergence threshold for eval_pedigree_1l and eval_pedigree_grad.  rel_eps rel_eps convergence threshold for eval_pedigree_1l and eval_pedigree_grad.  which_prof the index of the random effect which proportion of variance should be profiled.  indices zero-based vector with indices of which log marginal likelihood terms to include. Use NULL if all indices should be used.  maxvls_start, minvls_start     number of samples to use when finding the initial values for the optimization.  do_reorder TRUE if a heuristic variable reordering should be used. TRUE is likely the best value.  use_aprx TRUE if a less precise approximation of pnorm and qnorm should be used. This may reduce the computation time while not affecting the result much.  n_threads cluster_weights  number of threads to use.  lounder of threads to use.  method integer with the method to use. Zero yields randomized Korobov lattice rules while one yields scrambled Sobol sequences.  seed seed to pass to set_seed before each gradient and function evaluation. Use NULL if the seed should not be fixed.  verbose logical for whether output should be printed to the console during the estimation of the profile likelihood curve.  max_step integer scalar with the maximum number of steps to take in either directions. function to perform minimization with arguments like optim. BFGS is used with optim if this argument is NULL.  use_tilting TRUE if the minimax tilting method suggested by Botev (2017) should be used. See doi:10.1111/rssb.12162.  vls_scales  can be a numeric vector with a positive scalar for each cluster. Then vls_scales[i] * maxvls is used for cluster i rather than minvls and maxvls. Set vls_scales = NULL if the latter should be used. boundaries for the limits of the proportion. Has to be in between (0,1). This is useful particu	par	numeric vector with the maximum likelihood estimator e.g. from pedmod_opt.
alpha numeric scalar with the confidence level required.  abs_eps absolute convergence threshold for eval_pedigree_ll and eval_pedigree_grad.  rel_eps rel_eps convergence threshold for eval_pedigree_ll and eval_pedigree_grad.  which_prof the index of the random effect which proportion of variance should be profiled.  indices zero-based vector with indices of which log marginal likelihood terms to include. ## **Details**

The function is only useful when there is more than one type of random effect. If not, then pedmod\_profile can be used because of the scale invariance of the likelihood ratio.

#### Value

A list like pedmod\_profile.

#### See Also

pedmod\_opt, pedmod\_sqn, pedmod\_profile, and pedmod\_profile\_nleq.

```

pedmod\_sqn

Optimize the Log Marginal Likelihood Using a Stochastic Quasi-Newton Method

## **Description**

Optimizes eval\_pedigree\_11 and eval\_pedigree\_grad using a stochastic quasi-Newton method.

## Usage

```
pedmod_sqn(
  ptr,
  par,
  maxvls,
  abs_eps,
  rel_eps,
  step_factor,
  n_it,
  n_grad_steps,
  indices = NULL,
 minvls = -1L,
  n_{grad} = 50L,
  n_{\text{hess}} = 500L,
  do_reorder = TRUE,
  use_aprx = FALSE,
  n_{threads} = 1L,
  cluster_weights = NULL,
  fix = NULL,
  standardized = FALSE,
  minvls_hess = minvls,
 maxvls_hess = maxvls,
  abs_eps_hess = abs_eps,
  rel_eps_hess = rel_eps,
  verbose = FALSE,
  method = 0L,
  check_every = 2L * n_grad_steps,
  use_tilting = FALSE,
  vls_scales = NULL
)
```

## **Arguments**

object from pedigree\_ll\_terms. ptr starting values. par maxvls

maximum number of samples in the approximation for each marginal likelihood

term.

pedmod\_sqn 35

abs\_eps absolute convergence threshold for eval\_pedigree\_ll and eval\_pedigree\_grad. rel\_eps convergence threshold for eval\_pedigree\_ll and eval\_pedigree\_grad. rel\_eps factor used for the step size. The step size is step\_factor divided by the iterastep\_factor tion number. n\_it number of stochastic gradient steps to make. number of stochastic gradient steps to make between each Hessian approximan\_grad\_steps tion update. indices zero-based vector with indices of which log marginal likelihood terms to include. Use NULL if all indices should be used. minvls minimum number of samples for each marginal likelihood term. Negative values provides a default which depends on the dimension of the integration. number of log marginal likelihood terms to include in the stochastic gradient n\_grad number of log marginal likelihood terms to include in the gradients used for the n\_hess Hessian approximation update. This is set to the entire sample (or indices) if this is greater than or equal to half the number of log marginal likelihood terms. TRUE if a heuristic variable reordering should be used. TRUE is likely the best do\_reorder value. TRUE if a less precise approximation of pnorm and qnorm should be used. This use\_aprx may reduce the computation time while not affecting the result much. number of threads to use. n\_threads cluster\_weights numeric vector with weights for each cluster. Use NULL if all clusters have weight one. fix integer vector with indices of par to fix. This is useful for computing profile likelihoods. NULL yields all parameters. standardized logical for whether to use the standardized or direct parameterization. See standardized\_to\_direct and the vignette at vignette("pedmod", package = "pedmod"). minvls\_hess minvls argument to use when updating the Hessian approximation. maxvls\_hess maxvls argument to use when updating the Hessian approximation. abs\_eps\_hess abs\_eps argument to use when updating the Hessian approximation. rel\_eps\_hess rel\_eps argument to use when updating the Hessian approximation. verbose logical for whether to print output during the estimation. method integer with the method to use. Zero yields randomized Korobov lattice rules while one yields scrambled Sobol sequences. integer for the number of gradient steps between checking that the likelihood check\_every did increase. If not, the iterations are reset and the step-size is halved. use\_tilting TRUE if the minimax tilting method suggested by Botev (2017) should be used. See doi:10.1111/rssb.12162. vls\_scales can be a numeric vector with a positive scalar for each cluster. Then vls\_scales[i] \* minvls and vls\_scales[i] \* maxvls is used for cluster i rather than minvls

and maxvls. Set vls\_scales = NULL if the latter should be used.

36 pedmod\_sqn

#### **Details**

The function uses a stochastic quasi-Newton method like suggested by Byrd et al. (2016) with a few differences: Differences in gradients are used rather than Hessian-vector products, BFGS rather than L-BFGS is used because the problem is typically low dimensional, and damped BFGS updates are used (see e.g. chapter 18 of Nocedal and Wright, 2006).

Separate arguments for the gradient approximation in the Hessian update are provided as one may want a more precise approximation for these gradients. step\_factor likely depends on the other parameters and the data set and should be altered.

#### Value

A list with the following elements:

par estimated parameters.

omegas parameter estimates after each iteration.

H Hessian approximation in the quasi-Newton method. It should not be treated as

the Hessian.

```

## **Description**

Transform the parameters between the parameterizations that are used in the package.

## Usage

```
standardized_to_direct(par, n_scales, jacobian = FALSE)
direct_to_standardized(par, n_scales)
```

## **Arguments**

par concatenated vector with the fixed effect slopes and the scale parameters that

should be transformed.

n\_scales integer with the number of scale parameters.

jacobian logical indicating if the Jacobian matrix of transformation should be computed.

#### Value

standardized\_to\_direct: returns the parameters using the direct parameterizations. See vignette("pedmod", package = "pedmod") for the definition. There is an attribute called 'variance proportions' with the proportion of variance of each effect assuming that all the scale matrices are correlation matrices. There is an attribute called jacobian with the Jacobian matrix if jacobian is TRUE.

direct\_to\_standardized: the parameters using the standardized parameterizations. See vignette("pedmod", package = "pedmod") for the definition.

## **Examples**

```
# transform backwards and forwards
set.seed(1)
smp <- runif(10, -1, 1)
res <- standardized_to_direct(smp, 2L, jacobian = TRUE)
back_val <- direct_to_standardized(res, 2L)
all.equal(smp, back_val, check.attributes = FALSE)
res</pre>
```

unconnected\_partition Finds an Approximately Balanced Partition

## Description

Finds an Approximately Balanced Partition

unconnected\_partition 39

## Usage

```
unconnected_partition(
  from,
  to,
 weight_data = NULL,
  edge_weights = NULL,
 slack = 0,
 max_kl_it_inner = 50L,
 max_kl_it = 10000L,
  trace = 0L,
  init = integer()
)
unconnected_partition_pedigree(
  id,
  father.id,
 mother.id,
  id_weight = NULL,
  father_weight = NULL,
 mother_weight = NULL,
  slack = 0,
 max_kl_it_inner = 50L,
 max_kl_it = 10000L,
 trace = 0L,
  init = integer()
)
```

## **Arguments**

from	integer vector with one of the vertex ids.
to	integer vector with one of the vertex ids.
weight_data	list with two elements called "id" for the id and "weight" for the vertex weight. All vertices that are not in this list have a weight of one. Use NULL if all vertices have a weight of one.
edge_weights	numeric vector with weights for each edge. Needs to have the same length as from and to. Use NULL if all edges should have a weight of one.
slack	fraction between zero and 0.5 for the allowed amount of deviation from the balance criterion that is allowed to reduce the cost of the cut edges.
max_kl_it_inner	
	maximum number of moves to consider in each iteration when slack $> 0$ .
max_kl_it	maximum number of iterations to use when reducing the cost of the cut edges. Typically the method converges quickly and this argument is not needed.
trace	integer where larger values yields more information printed to the console during the procedure.
init	integer vector with ids that one of the two sets in the partition should start out with.

id integer vector with the child id.
 father.id integer vector with the father id. May be NA if it is missing.
 mother.id integer vector with the mother id. May be NA if it is missing.
 id\_weight numeric vector with the weight to use for each vertex (individual). NULL yields a weight of one for all.
 father\_weight weights of the edges created between the fathers and the children. Use NULL if all should have a weight of one.
 mother\_weight weights of the edges created between the mothers and the children. Use NULL if all should have a weight of one.

#### Value

A list with the following elements:

balance\_criterion

value of the balance criterion.

removed\_edges 2D integer matrix with the removed edges.

set\_1, set\_2 The two sets in the partition.

#### See Also

max\_balanced\_partition.
